On distance Laplacian spectrum of zero divisor graphs of the ring $\mathbb{Z}_n$

Pirzada S., Rather B.A., Chishti T.A.

For a finite commutative ring $\mathbb{Z}_n$ with identity 1 ≠ 0, the zero divisor graph $\Gamma(\mathbb{Z}_n)$ is a simple connected graph having vertex set as the set of non-zero zero divisors, where two vertices $x$ and $y$ are adjacent if and only if $xy = 0$. We find the distance Laplacian spectrum of the zero divisor graphs $\Gamma(\mathbb{Z}_n)$ for different values of $n$. Also, we obtain the distance Laplacian spectrum of $\Gamma(\mathbb{Z}_n)$ for $n = p^z, z \geq 2$, in terms of the Laplacian spectrum. As a consequence, we determine those $n$ for which zero divisor graph $\Gamma(\mathbb{Z}_n)$ is distance Laplacian integral.

Key words and phrases: Laplacian matrix, distance Laplacian matrix, commutative ring, zero divisor graph.

1 Introduction

In this paper, we consider only connected, simple and finite graphs. A graph is denoted by $G = (V(G), E(G))$, where $V(G) = \{v_1, v_2, \ldots, v_n\}$ is its vertex set and $E(G)$ is its edge set. The order of $G$ is $n = |V(G)|$ and its size is $m = |E(G)|$. The set of vertices adjacent to $v \in V(G)$, denoted by $N(v)$, is the neighborhood of $v$. The degree of $v$, denoted by $d_G(v)$ (we simply write $d_v$ if it is clear from the context), means the cardinality of $N(v)$. A graph is regular if each of its vertices has the same degree. The adjacency matrix $A = (a_{ij})$ of $G$ is a $(0,1)$-square matrix of order $n$ whose $(i,j)$-entry is equal to 1 if $v_i$ is adjacent to $v_j$ and equal to 0, otherwise. Let $\text{Deg}(G) = \text{diag}(d_1, d_2, \ldots, d_n)$ be the diagonal matrix of vertex degrees $d_i = d_G(v_i), i = 1,2,\ldots,n$ associated to $G$. The matrices $L(G) = \text{Deg}(G) - A(G)$ and $Q(G) = \text{Deg}(G) + A(G)$ are respectively the Laplacian and the signless Laplacian matrices and these matrices are real symmetric and positive semi-definite. We take $0 = \lambda_n \leq \lambda_{n-1} \leq \cdots \leq \lambda_1$ to be the Laplacian eigenvalues of $L(G)$.

In $G$, the distance between two vertices $u,v \in V(G)$, denoted by $d_{uv}$, is defined as the length of a shortest path between $u$ and $v$. The diameter of $G$ is the maximum distance between any two vertices of $G$. The distance matrix of $G$, denoted by $D(G)$, is defined as $D(G) = (d_{uv})_{u,v \in V(G)}$. The transmission $\text{Tr}_G(v)$ of a vertex $v$ is defined to be the sum of the distances from $v$ to all other vertices in $G$, i.e., $\text{Tr}_G(v) = \sum_{u \in V(G)} d_{uv}$. A graph $G$ is said to be $k$-transmission regular if $\text{Tr}_G(v) = k$, for each $v \in V(G)$. For any vertex $v_i \in V(G)$, the transmission $\text{Tr}_G(v_i)$ is called the transmission degree, shortly denoted by $Tr_i$ and the sequence $\{Tr_1, Tr_2, \ldots, Tr_n\}$ is called the transmission degree sequence of the graph $G$.

Let \( Tr(G) = \text{diag}(Tr_1, Tr_2, \ldots , Tr_n) \) be the diagonal matrix of vertex transmissions of \( G \). Aouchiche M. and Hansen P. [2] introduced the Laplacian and the signless Laplacian for the distance matrix of a connected graph. The matrix \( D^L(G) = Tr(G) - D(G) \) is called the \textit{distance Laplacian matrix} of \( G \), while the matrix \( D^Q(G) = Tr(G) + D(G) \) is called the \textit{distance signless Laplacian matrix} of \( G \). These matrices are real symmetric and positive semi-definite, so we order the distance Laplacian eigenvalues as \( \rho_1 \geq \cdots \geq \rho_{n-1} \geq \rho_n = 0 \). More about \( D^L(G) \) can be seen in [2,3,7,11] and the references therein.

Let \( R \) be a commutative ring with multiplicative identity \( 1 \neq 0 \). A non-zero element \( x \in R \) is called a zero divisor of \( R \) if there exists a non-zero \( y \in R \) such that \( xy = 0 \). The zero divisor graph \( \Gamma(R) \) of a commutative ring \( R \) is the graph whose vertex set is the set of non-zero zero divisors of \( R \) and two vertices \( x \) and \( y \) are adjacent if and only if \( xy = 0 \) [1]. The zero divisor graph \( \Gamma(Z_n) \) is of order \( n - \phi(n) - 1 \), where \( \phi \) is Euler’s totient function and \( Z_n \) is the integer modulo ring.

In a graph \( G \), we write \( x \sim y \) if vertices \( x \) and \( y \) are adjacent. We use standard notation, \( K_n, K_{a,b} \), for complete graph and complete bipartite graph. Other undefined notations and terminology from algebraic graph theory, algebra and matrix theory can be found in [4,6,8,10].

Investigation of spectral properties of matrices associated to graphs is always interesting and challenging. Since it is not always possible to obtain all the zeros of the characteristic polynomial of a matrix whose order is more than 4, therefore in most of the cases the study of spectra is restricted to certain families of graphs. Even at times the problem becomes difficult for a particular class of graphs. In this direction, we have considered the problem to investigate the distance Laplacian spectrum of zero divisor graphs associated to the ring \( Z_n \). We note that the graphs associated to different algebraic structures, for instance, power graphs and commuting graphs of groups, zero divisor graphs of rings have helped to solve several problems both in algebra and combinatorics. Adjacency eigenvalues of zero divisor graphs were first discussed by Young M. [9]. Laplacian, signless Laplacian and distance signless Laplacian spectral properties of zero divisor graphs were investigated in [5,11–13].

The rest of the paper is organized as follows. In Section 2, we discuss the distance Laplacian spectrum of the zero divisor graph \( \Gamma(Z_n) \) for some values of \( n \in \{pq, p^2q, (pq)^2, p^z, z \geq 2\} \) and show that \( \Gamma(Z_n) \), for \( n \in \{p^2, pq\} \), is distance Laplacian integral. We have used computational software Mathematica for computing approximate eigenvalues and characteristic polynomials of various matrices.

## 2 The distance Laplacian spectrum of the zero divisor graphs

The join of two graphs \( G_1 \) and \( G_2 \), denoted by \( G_1 \vee G_2 \), is the union of \( G_1 \) and \( G_2 \) together with edges from each vertex of \( G_1 \) to every vertex of \( G_2 \). The following result concerns with the distance Laplacian spectrum of the join of two graphs.

**Theorem 1.** Let \( G_1 \) and \( G_2 \) be graphs with \( n_1 \) and \( n_2 \) vertices, respectively. Let \( \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_{n_1} = 0 \) and \( \mu_1 \geq \mu_2 \geq \cdots \geq \mu_{n_2} = 0 \) be the Laplacian eigenvalues of \( G_1 \) and \( G_2 \). Then the distance Laplacian characteristic polynomial of \( G_1 \vee G_2 \) is

\[
P_L^{G_1 \vee G_2}(t) = t(t-n)(t-2n + n_1 + \lambda)^{n_1-1}(t-2n + n_1 + \mu)^{n_2-1},
\]

where \( \lambda \) and \( \mu \) are the non-zero Laplacian eigenvalues of \( G_1 \) and \( G_2 \), respectively.
Proof. Let $G_1 \vee G_2$ be the join of the graphs $G_1$ and $G_2$. This is clearly a graph of diameter 2. Let $V(G_1) = \{v_1, v_2, \ldots, v_{n_1}\}$ and $V(G_2) = \{u_1, u_2, \ldots, u_{n_2}\}$ be the vertex sets of $G_1$ and $G_2$, respectively. So $V(G) = V(G_1) \cup V(G_2)$. It is easy to see that $Tr(v) = 2n - n_2 - 2 - d(v)$, for each $v \in V(G_1)$ and $Tr(u) = 2n - n_2 - 2 - d(u)$, for each $u \in V(G_2)$. Label the vertices of $G_1 \vee G_2$, so that the first $n_1$ vertices are from $G_1$. With this labelling, the distance Laplacian matrix can be put in the form

$$D^L(G_1 \vee G_2) = \left( \begin{array}{cc} (2n - n_2)I_{n_1} - 2J_{n_1} - L(G_1) & -J_{n_1 \times n_2} \\ -J_{n_2 \times n_1} & (2n - n_1)I_{n_2} - 2J_{n_2} - L(G_2) \end{array} \right),$$

where $L(G_2)$, $I_n$, and $J_{n \times n}$ are respectively the distance Laplacian matrix, identity matrix and the matrix whose each entry equals 1.

From Theorem 1, we observe that the distance Laplacian characteristic polynomial of $G_1 \vee G_2$ is

$$\det\left(\lambda I - D^L(G_1 \vee G_2)\right) = (\lambda - \lambda_1)(\lambda - \lambda_2) \cdots (\lambda - \lambda_{2n-2}),$$

where $\lambda_i$ are the eigenvalues of $D^L(G_1 \vee G_2)$.

This implies that $2n - n_2 - \lambda_k$, $1 \leq k \leq n_1 - 1$, is a distance Laplacian eigenvalue of $D^L(G_1 \vee G_2)$ with multiplicity $n_1 - 1$. Similarly, $2n - n_1 - \mu_j$, $1 \leq j \leq n_2 - 1$, is a distance Laplacian eigenvalue of $D^L(G_1 \vee G_2)$.

This completes the proof.

If $K_{a,b}$ is the complete bipartite graph with partite sets of cardinality $a$ and $b$, then clearly $K_{a,b} = K_a \vee K_b$. From Theorem 1, taking $n_1 = a$, $n_2 = b$, and $\lambda_i = \mu_j = 0$ for each $i, j$, we observe that the distance Laplacian characteristic polynomial of $K_{a,b}$ is

$$D^L(K_{a,b}) = 1.$$

A complete split graph, denoted by $CS_{\omega,n-\omega}$, is the graph consisting of a clique on $\omega$ vertices and an independent set\(^1\) on the remaining $n - \omega$ vertices, such that each vertex of the clique is adjacent to every vertex of the independent set. Note that $CS_{\omega,n-\omega} = K_\omega \vee K_{n-\omega}$. Again, from Theorem 1, we observe that the distance Laplacian characteristic polynomial of $CS_{\omega,n-\omega}$ is

$$P^L_{CS_{\omega,n-\omega}}(t) = t(t-n)^\omega (t-2n+\omega)^{n-\omega-1}.$$

This is because the Laplacian spectrum of $K_\omega$ is $\{\omega^{\omega-1}, 0\}$, apply Theorem 1 by taking $n_1 = \omega$, $n_2 = n - \omega$, $\lambda_i = \omega$ for $i = 2, \ldots, \omega$, and $\mu_j = 0$ for $j = 2, 3, \ldots, n - \omega$.

\(^1\)A subset of vertices of a graph is said to be an independent set if the subgraph induced by them is an empty graph.
The joined union of graphs is defined as follows [14]. Let $G(V, E)$ be a graph of order $n$ and $G_i(V_i, E_i)$ be graphs of order $m_i$, where $i = 1, \ldots, n$. The joined union $G[G_1, \ldots, G_n]$ is the graph $H = (W, F)$ with

$$W = \bigcup_{i=1}^{n} V_i \quad \text{and} \quad F = \bigcup_{i=1}^{n} E_i \cup \bigcup_{\{v_i, v_j\} \in E} V_i \times V_j.$$ 

In other words, the joined union is the union of graphs $G_1, \ldots, G_n$ together with the edges between the vertices $v_i \in V(G_i)$ and $v_j \in V(G_j)$ whenever $v_i$ and $v_j$ are adjacent in $G$.

The following result from [7] gives the distance Laplacian spectrum of $G[G_1, \ldots, G_n]$ in terms of the Laplacian spectrum of the graphs $G_i$, for $i = 1, 2, \ldots, n$.

**Theorem 2** ([7]). Let $G$ be a graph of order $n$ having vertex set $V(G) = \{v_1, \ldots, v_n\}$. Let $G_i$ be a graph of order $m_i$ with Laplacian eigenvalues $\mu_{i1} \geq \mu_{i2} \geq \ldots \geq \mu_{im_i}$, where $i = 1, 2, \ldots, n$. The distance Laplacian spectrum of the joined union $G[G_1, \ldots, G_n]$ consists of the eigenvalues $2m_i - \mu_{jk} + \alpha_i$ for $i = 1, \ldots, n$ and $k = 1, 2, 3, \ldots, m_i - 1$, where $\alpha_i = \sum_{k=1, k \neq i}^{n} m_k d_G(v_i, v_k)$. The remaining $n$ eigenvalues are given by the matrix

$$M = \begin{pmatrix}
\alpha_1 & -m_2 d_G(v_1, v_2) & \ldots & -m_n d_G(v_1, v_n) \\
-m_1 d_G(v_2, v_1) & \alpha_2 & \ldots & -m_n d_G(v_2, v_n) \\
\vdots & \vdots & \ddots & \vdots \\
-m_1 d_G(v_n, v_1) & -m_2 d_G(v_n, v_2) & \ldots & \alpha_n
\end{pmatrix}.$$ 

An integer $d$ is a proper divisor of $n$ if $d$ divides $n$, written as $d|n$, for $1 < d < n$. Let $Y_n$ be the simple graph with vertex set $\{d_1, d_2, \ldots, d_t\}$ and two distinct vertices in $Y_n$ are adjacent if and only if $n|d_i d_j$. If the prime power factorization of $n = p_1^{n_1} p_2^{n_2} \ldots p_r^{n_r}$, where $r, n_1, n_2, \ldots, n_r$ are positive integers and $p_1, p_2, \ldots, p_r$ are distinct prime numbers, the size of $Y_n$ is given by $|V(Y_n)| = \prod_{i=1}^{r} (n_i + 1) - 2$. For $1 \leq i \leq t$, we consider the sets $A_{d_i} = \{x \in \mathbb{Z}_n : (x, n) = d_i\}$. We see that $A_{d_i} \cap A_{d_j} = \emptyset$, when $i \neq j$, implying that the sets $A_{d_1}, A_{d_2}, \ldots, A_{d_t}$ are pairwise disjoint and partitions the vertex set of $\Gamma(\mathbb{Z}_n)$ as $V(\Gamma(\mathbb{Z}_n)) = A_{d_1} \cup A_{d_2} \cup \cdots \cup A_{d_t}$. From definition of $A_{d_i}$, a vertex of $A_{d_i}$ is adjacent to a vertex of $A_{d_j}$ in $\Gamma(\mathbb{Z}_n)$ if and only if $n$ divides $d_i d_j$ for $i, j \in \{1, 2, \ldots, t\}$.

The following result from [9] gives the cardinality of $A_{d_i}$.

**Lemma 1** ([9]). Let $d_i$ be the proper divisor of $n$. Then

$$|A_{d_i}| = \phi \left( \frac{n}{d_i} \right)$$

for $1 \leq i \leq t$.

The next lemma from [5] shows that the induced subgraphs $\Gamma(A_{d_i})$ of $\Gamma(\mathbb{Z}_n)$ are either cliques or their complements.
Lemma 2 ([5]). The following hold.

(i) For \( i \in \{1,2,\ldots,t\} \), the induced subgraph \( \Gamma(A_{d_i}) \) of \( \Gamma(Z_n) \) on the vertex set \( A_{d_i} \) is either a complete graph \( K_{\phi(d_i)} \) or its complement \( \overline{K}_{\phi(d_i)} \). Indeed, \( \Gamma(A_{d_i}) = K_{\phi(d_i)} \) if and only if \( n \) divides \( d_i^2 \).

(ii) For \( i, j \in \{1,2,\ldots,t\} \) with \( i \neq j \), a vertex of \( A_{d_i} \) is adjacent to either all or none of the vertices of \( A_{d_j} \) in \( \Gamma(Z_n) \).

The following lemma shows that \( \Gamma(Z_n) \) is the joined union of certain complete graphs and null graphs.

Lemma 3 ([5]). Let \( \Gamma(A_{d_i}) \) be the induced subgraph of \( \Gamma(Z_n) \) on the vertex set \( A_{d_i} \) for \( 1 \leq i \leq t \). Then
\[
\Gamma(Z_n) = Y_n[\Gamma(A_{d_1}), \Gamma(A_{d_2}), \ldots, \Gamma(A_{d_t})].
\]

We consider an example to find the distance Laplacian spectrum with the help of Theorem 2. We know that \( \Gamma(Z_n) \) is a complete graph if and only if \( n = p^2 \) for some prime \( p \). Further, the adjacency spectrum of \( K_\omega \) and \( \overline{K}_\omega \) on \( \omega \) vertices are \( \{\omega - 1, -1, \omega^{-1}\} \) and \( \{0, \omega\} \), respectively. So, by Theorem 2, out of \( n - \phi(n) - 1 \) number of distance Laplacian eigenvalues of \( \Gamma(Z_n) \), \( n - \phi(n) - 1 - t \) of them are known to be positive integers. The remaining \( t \) distance Laplacian eigenvalues of \( \Gamma(Z_n) \) will count from the zeros of the characteristic polynomial of the equitable quotient matrix \( M \).

Example 1. Distance Laplacian eigenvalues of \( \Gamma(Z_{30}) \).

Let \( n = 30 \). Then \( 2, 3, 5, 6, 10 \) and \( 15 \) are the proper divisors of \( n \) and \( Y_n \) is the graph \( G_6 : 3 \sim 10 \sim 6 \sim 5, 10 \sim 15 \sim 2 \) and \( 6 \sim 15 \), that is, \( Y_n \) is the triangle graph having a pendent edge at each vertex of the triangle. Indexing the vertices by increasing proper divisor sequence and applying Lemma 3, we have
\[
\Gamma(Z_{30}) = Y_{30}[K_6, K_4, K_2, K_4, K_2, K_1].
\]

By Theorem 2, the distance Laplacian spectrum of \( \Gamma(Z_{30}) \) consists of the eigenvalues
\[
\{48^{[4]}, 47^{[7]}, 37^{[3]}, 33\},
\]
and the remaining six eigenvalues are the zeros of the characteristic polynomial of the following matrix
\[
\begin{pmatrix}
31 & -12 & -6 & -8 & -4 & -1 \\
-24 & 42 & -6 & -8 & -2 & -2 \\
-24 & -12 & 46 & -4 & -4 & -2 \\
-16 & -8 & -2 & 29 & -2 & -1 \\
-16 & -4 & -4 & -4 & 29 & -1 \\
-8 & -8 & -4 & -4 & -2 & 26
\end{pmatrix}.
\]

The characteristic polynomial of matrix (1) is
\[
x^6 - 203x^5 + 16167x^4 - 631097x^3 + 12078472x^2 - 90732012x.
\]
and its approximated zeros are

\[ \{54.8984, 52.8576, 37.2458, 31.1478, 27.0505, 0.0000\}. \]

Now, we find the distance Laplacian spectrum of \( \Gamma(Z_n) \) for \( n \in \{pq, p^2q, (pq)^2, p^z, z \geq 2\} \) with the help of Theorems 1 and 2. Consider \( n = pq \), where \( p \) and \( q, p < q \), are distinct primes. We use either Theorem 1 or Theorem 2. By Lemmas 2 and 3, we have

\[ \Gamma(Z_{pq}) = Y_{pq}[\Gamma(A_p), \Gamma(A_q)] = K_2[\overline{K}_{\phi(p)}, \overline{K}_{\phi(q)}] = \overline{K}_{\phi(p)} \vee \overline{K}_{\phi(q)} = K_{\phi(p)\phi(q)}. \]  

(2)

**Lemma 4.** The distance Laplacian spectrum of \( \Gamma(Z_n) \) consists of the eigenvalues \( 2n - q + 1 \) with multiplicity \( p - 2 \), the eigenvalue \( 2n - p + 1 \) with multiplicity \( q - 2 \), and the eigenvalues \( \{0, n\} \).

**Proof.** Let \( n = pq \), where \( p \) and \( q, p < q \), are distinct primes. Then the proper divisors of \( n \) are \( p \) and \( q \), so \( Y_{pq} \) is \( K_2 \). By equation (2) and Theorem 1 the result follows. \( \square \)

The next result gives the distance Laplacian spectrum of \( \Gamma(Z_{p^2q}) \) for \( n = p^2q \).

**Lemma 5.** The distance Laplacian spectrum of \( \Gamma(Z_{p^2q}) \) is

\[ \{(3pq + 2p^2 - 2p - 2q)^{[p^2-p-1]}, (pq + 2p^2 - 2p)^{[p-2]}, (2pq + p^2 - 2p - 1)^{[q-2]}, (3p^2 + 2pq - 4p - 1)^{pq-p-1}, x_1 \geq x_2 \geq x_3 \geq x_4 = 0\}, \]

where \( x_1, x_2, x_3 \) are the non-zero zeros of the characteristic polynomial of the quotient matrix \( M(P_4) \).

**Proof.** Let \( n = p^2q \), where \( p \) and \( q \) are distinct primes. Since proper divisors of \( n \) are \( p, q, pq, p^2 \), so \( Y_{p^2q} \) is the path \( P_4 : q \sim p^2 \sim pq \sim p \). By Lemma 3, we have

\[ \Gamma(Z_{p^2q}) = Y_{p^2q}[\Gamma(A_q), \Gamma(A_{pq}), \Gamma(A_p)] = P_4[\overline{K}_{\phi(p^2)}, \overline{K}_{\phi(q)}, K_{\phi(p)}], \overline{K}_{\phi(pq)}], \]

with respective orders \( m_1 = \phi(p^2) \), \( m_2 = \phi(q) \), \( m_3 = \phi(p) \) and \( m_4 = \phi(pq) \). Further, we see that \( (a_1, a_2, a_3, a_4) = (3pq - p - 2q, 2pq + p^2 - 2p - 2q + 1, 2p^2 + pq - 3p, 3p^2 + 2q - 2p - 3) \) and by Theorem 2, distance Laplacian spectrum of \( \Gamma(Z_{p^2q}) \) consists of the eigenvalues \( 3pq + 2p^2 - 2p - 2q, pq + 2p^2 - 2p, 2pq + p^2 - 2p - 1, 3p^2 + 2pq - 4p - 1 \) with multiplicities \( p^2 - p - 1 \), \( p - 2 \), \( q - 2 \), \( pq - p - q \), respectively. The remaining eigenvalues are given by the following of the equitable quotient matrix

\[ M(P_4) = \begin{pmatrix}
  a_1 & -\phi(q) & -2\phi(p) & -3\phi(pq) \\
  -\phi(p^2) & a_2 & -\phi(p) & -2\phi(pq) \\
  -2\phi(p^2) & -\phi(q) & a_3 & -\phi(pq) \\
  -3\phi(p^2) & -2\phi(q) & -\phi(p) & a_4
\end{pmatrix}. \]

Clearly, each row sum of \( M(P_4) \) is zero, so that 0 is its eigenvalue and the remaining eigenvalues are the non-zero zeros of the characteristic polynomial of \( M(P_4) \). \( \square \)
Lemma 6. The distance Laplacian spectrum of $\Gamma(Z_{(pq)^2})$ is

\[
\{ (3p^2q + 2pq^2 + 2q - 5p - 2pq)\phi(pq^2)^{-1}, (3p^2q + 2pq^2 - q - 2p^2 - 2pq)\phi(p^2)^{-1}, (3p^2q + 2pq^2 - q - 3pq - 1)\phi(pq^2)^{-1}, (2p^2q + 3pq^2 + q - 2q^2 - 3pq - 1)\phi(p^2)^{-1}, (2p^2q + 3pq^2 + p - 6q - 4pq)\phi(pq)^{-1}, (2p^2q + 3pq^2 - p - q - pq)\phi(pq)^{-1}, (p^2q + 2pq^2 - 2pq - 1)\phi(q)^{-1}\}
\]

and the zeros of the characteristic polynomial of the matrix $M(G_7)$ in (2).

Proof. Let $n = (pq)^2$, where $p$ and $q$, $p < q$, are distinct primes. Since the proper divisors of $n$ are $p$, $p^2$, $q$, $q^2$, $pq$, $pq^2$ and $p^2q$, so $Y_{(pq)^2}$ is the graph $G_7 : q \sim p^2q \sim q \sim p^2 \sim pq^2 \sim p$, $p^2q \sim pq$. We name the vertices in $G_7$ according to the proper divisor sequence, so by Lemma 3, we have

\[
\Gamma(Z_{(pq)^2}) = Y_{(pq)^2}\Gamma(A_p), \Gamma(A_{p^2}), \Gamma(A_q), \Gamma(A_{pq}), \Gamma(A_{pq^2}), \Gamma(A_{p^2q})
\]

\[
= G_7[\mathcal{R}_{\phi(pq^2)}, \mathcal{R}_{\phi(q^2)}, \mathcal{R}_{\phi(p^2)}, K_{\phi(pq)}, K_{\phi(p)}, K_{\phi(q)}].
\]

By Theorem 2, we have

\[
(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6, \alpha_7) = (3p^2q + 2q^2 - 5p, 3p^2q + 2pq^2 + q - 2p^2 - 2pq, 3pq^2 + 2p^2 - 2p - q - pq - 1, 2p^2q + 3pq^2 + 2p + q - 2p^2 - 2q^2 - 3pq - 1, 2p^2q + 3pq^2 + 2p - 5q - 5pq - 1, 2p^2q + pq^2 - 2p - q, 2p^2q + pq^2 - 2p - q).
\]

Again, by Theorem 2, the distance Laplacian spectrum of $\Gamma(Z_{(pq)^2})$ consists of the eigenvalue $2\phi(pq^2) + \alpha_1 = 3p^2q + 2pq^2 + 2q - 5p - 2pq$ with multiplicity $\phi(pq^2) - 1$, the eigenvalue $3p^2q + 2pq^2 - q - 2p^2 - 2pq$ with multiplicity $\phi(q^2) - 1$, the eigenvalue $3p^2q + 2pq^2 - q - 3pq - 1$ with multiplicity $\phi(pq^2) - 1$, the eigenvalue $2p^2q + 3pq^2 + q - 2q^2 - 3pq - 1$ with multiplicity $\phi(p^2) - 1$, the eigenvalue $2p^2q + 3pq^2 - p - 6q - 4pq$ with multiplicity $\phi(pq) - 1$, the eigenvalue $2p^2q + 3pq^2 - p - q - pq$ with multiplicity $\phi(p) - 1$, the eigenvalue $p^2q + 2pq^2 - 2pq - 1$ with multiplicity $\phi(q) - 1$ and the remaining seven eigenvalues are given by the following matrix

\[
M(G_7) = \begin{pmatrix}
\alpha_1 & -2\phi(p^2) & -3\phi(pq^2) & -3\phi(p^2) & -3\phi(pq) & -\phi(p) & -2\phi(q) \\
-2\phi(pq^2) & \alpha_2 & -3\phi(p^2q) & -\phi(p^2) & -3\phi(pq) & -\phi(p) & -2\phi(q) \\
-3\phi(p^2q) & -3\phi(q^2) & \alpha_3 & -2\phi(p^2) & -2\phi(pq) & -2\phi(p) & -\phi(q) \\
-3\phi(pq^2) & -\phi(q^2) & -2\phi(p^2q) & \alpha_4 & -2\phi(pq) & -2\phi(p) & -\phi(q) \\
-3\phi(pq^2) & -3\phi(q^2) & -2\phi(p^2q) & -2\phi(p^2) & \alpha_5 & -2\phi(p) & -\phi(q) \\
-\phi(pq^2) & -\phi(q^2) & -2\phi(p^2q) & -2\phi(p^2) & -2\phi(pq) & \alpha_6 & -\phi(q) \\
-2\phi(pq^2) & -2\phi(q^2) & -\phi(p^2q) & -\phi(p^2) & -\phi(pq) & -\phi(p) & \alpha_7
\end{pmatrix}.
\]

By using values of $\alpha_i$s, we see that each row sum of the matrix $M(G_7)$ is zero, so 0 is its distance Laplacian eigenvalue and other six eigenvalues are the non-zero zeros of the characteristic polynomial of the above given matrix. 

\(\square\)
Now, we find the distance Laplacian spectrum of $\Gamma(Z_n)$ for $n = p^z$, $z \geq 3$. We consider $n = p^{2m}$ and similar type of analysis can be done for $n = p^{2m+1}$. If $n = p^{2m}$, then the divisor sequence is \{\(p, p^2, \ldots, p^{2m-1}\)\} and vertex $p^i$ is adjacent to vertex $p^j$ in $Y_{p^{2m}}$ for each $j \geq 2m - i$ with $1 \leq i \leq 2m - 1$ and $i \neq j$. By Lemma 1, order of $G_i$ is $m_i = \phi(p^{2m-i})$ for $i = 1, 2, \ldots, 2m-1$. Also, for $i = 1, 2, \ldots, m-1$, $G_i = \bar{K}_{\phi(p^{2m-i})}$ and for $i = m, \ldots, 2m-1$, $G_i = K_{\phi(p^{2m-i})}$. From Theorem 2, the distance Laplacian spectrum of $\Gamma(Z_n)$ consists of $\rho_i = 2p^{2m-1} - p^i - 1$, with respective multiplicities $\phi(p^{2m-i}) - 1$ for $i = 1, 2, \ldots, 2m-1$, and the remaining eigenvalues are given by equitable quotient of $\Gamma(Z_n)$. We observe that $\rho_i$ adds the missing entry in the definition of $\alpha_i$ in Theorem 2.

Now, the remaining eigenvalues of the quotient matrix can be found in several ways. One way is to use the mathematical induction and show that the eigenvalues of quotient matrix are those of $\rho_i$ together with 0 and each with multiplicity 1 except when $i \neq m$. Another way is to construct $\Gamma(Z_n)$ by using iteration join graphs as in [5] and use Theorem 1 continuously till we get all the eigenvalues. The natural way is to see that $\Gamma(Z_n)$ is a graph of diameter two, so that distance Laplacian spectrum of $\Gamma(Z_n)$ can be found in terms of spectrum of the Laplacian matrix. For that we need the following results.

**Theorem 3** ([2]). Let $G$ be a connected graph on $n$ vertices with diameter at most two. Then the distance Laplacian spectrum of $G$ is

\[
2n - \lambda_{n-1} \geq 2n - \lambda_{n-2} \geq \ldots \geq 2n - \lambda_1 > \rho_n = 0.
\]

A matrix of order $n$ with real entries is said to be integral, if all its eigenvalues are integers. Likewise, a graph $G$ is said to be integral if its associated matrix is integral.

A consequence of the above result is the following, whose proof is trivial.

**Corollary 1.** Let $G$ be graph on $n$ vertices with diameter at most two. Then $G$ is Laplacian integral if and only if $G$ is distance Laplacian integral.

**Theorem 4** ([5]). Let $n = p^z$ where $p$ is prime and $z \geq 2$ is a positive integer. Then the following hold.

(i) If $z = 2$, then the Laplacian spectrum of $\Gamma(Z_n)$ is \{(\(p-1\))^{p-2}, 0\}.

(ii) If $z = p^{2m}$ for some positive integer $m \geq 2$, then the Laplacian spectrum of $\Gamma(Z_n)$ consists of the eigenvalue 0, the eigenvalue $p^i - 1$ with multiplicity $\phi(p^{2m-i})$, where $i = 2m - 1, 2m - 2, \ldots, m + 2, m + 1, m - 1, m - 2, \ldots, 1$ and the eigenvalue $p^m - 1$ with multiplicity $\phi(p^m) - 1$.

(iii) If $z = p^{2m+1}$ for some positive integer $m \geq 1$, then the distance Laplacian spectrum of $\Gamma(Z_n)$ consists of the eigenvalue 0, the eigenvalue $p^i - 1$ with multiplicity $\phi(p^{2m+1-i})$, where $i = 2m, 2m - 1, \ldots, m + 2, m + 1, m - 1, m - 2, \ldots, 1$ and the eigenvalue $p^m - 1$ with multiplicity $\phi(p^{m+1}) - 1$. 
Theorem 5. Let \( n = p^2 \) where \( p \) is prime and \( z \geq 1 \) is a positive integer. Then the following hold.

(i) If \( z = 2 \), then the distance Laplacian spectrum of \( \Gamma(Z_n) \) is \( \{(p-1)|p^2-1|,0\} \).

(ii) If \( z = p^{2m} \) for some positive integer \( m \geq 2 \), then the distance Laplacian spectrum of \( \Gamma(Z_n) \) consists of the simple eigenvalue 0, the eigenvalue \( 2p^{2m-1} - p^{2m-i} - 1 \) with multiplicity \( \phi(p^i) \) for \( i = 2m - 1, 2m - 2, \ldots, m + 1, m - 1, \ldots, 2, 1 \) and the eigenvalue \( 2p^{2m-1} - p^m - 1 \) with multiplicity \( \phi(p^m) - 1 \).

(iii) If \( z = p^{2m} \) for some positive integer \( m \geq 2 \), then the distance Laplacian spectrum of \( \Gamma(Z_n) \) consists of the simple eigenvalue 0, the eigenvalue \( 2p^{2m-1} - p^{2m-i} - 1 \) with multiplicity \( \phi(p^i) \) for \( i = 2m, 2m - 1, \ldots, m + 1, m - 1, \ldots, 2, 1 \) and the eigenvalue \( 2p^{2m-1} - p^m - 1 \) with multiplicity \( \phi(p^{m+1}) - 1 \).

Proof. (i) Since \( \Gamma(Z_{p^2}) = \Gamma(A_p) \) is the complete graph \( K_{p-1} \) for any prime \( p \), so the result follows for \( p > 2 \).

The other cases follow from Theorem 3 and Theorem 4 and using the fact that order of \( Z_n \) is \( n = \phi(n) - 1 \).

Now, for \( n = p^3 \), by Lemma 3 we have

\[
\Gamma(Z_{p^3}) = \bigvee_{p^3} K_p = [\Gamma(A_p), \Gamma(A_{p^2})] = K_{p\phi(p^2)} = K_{p(p-1)} \sqrt{K_{p-1}}.
\]

This implies that \( \Gamma(Z_{p^3}) \) is a complete split graph of order \( p^2 - 1 \), having independent set of cardinality \( p(p-1) \) and clique of size \( p - 1 \). By Theorem 1, distance Laplacian spectrum of \( \Gamma(Z_n) \) is \( \{(2p^2 - p + 1)|p^2 - p - 2|, (p^2 - 1)|p^2 - 2|, 0\} \).

From the facts and discussions above, we have the following observation.

Corollary 2. \( \Gamma(Z_n) \) is distance Laplacian integral if and only if \( n \) is prime power or product of two distinct primes.

Proof. If \( n \) is either prime power or product of two distinct primes, then by Lemma 4 and Theorem 5, it follows that the distance Laplacian eigenvalues of \( \Gamma(Z_n) \) are integers. Also, by Lemma 5, for \( p = 2^2 \), \( \Gamma(Z_{4q}) \) is the complete bipartite graph and its distance Laplacian eigenvalues are integers. For other way round, if \( n \) is the product of three primes, then by Example 1, we get some non-integer distance Laplacian eigenvalues of \( \Gamma(Z_{pqr}) \), where \( p, q, r, p < q < r \) are primes. More generally, if \( n = p_1^{n_1}p_2^{n_2} \ldots p_r^{n_r} \), where \( r, n_1, \ldots, n_r \) are non-negative integers and \( p_i, i = 1, 2, \ldots, r \), are primes, then for \( r \geq 3 \), \( \Gamma(Z_n) \) contains the triangle \( \frac{n}{p_1} \sim \frac{n}{p_2} \sim \frac{n}{p_3} \sim \frac{n}{p_1p_2} \), which implies that \( \Gamma(Z_n) \) is not complete bipartite and is distance Laplacian integral. Similarly, \( \Gamma(Z_{p_1^{n_1}p_2^{n_2}}), n_1, n_2 \geq 2 \), contains the triangle \( p_1^{r_1}p_2^{r_2} \sim p_1p_2^{r_2} \sim p_1^{r_1}p_2^{r_2} \sim p_1^{r_1-1}p_2^{r_2} \), so its zero divisor graph is not complete bipartite. Again, for \( n = p^2q \) or \( n = pq^2 \), by Lemma 6, the zero divisor graph is not integral. Therefore, \( \Gamma(Z_n) \) is distance Laplacian integral only for \( n = p^2, pq, 4q \) with \( p < q \) being primes.

Another consequence of Theorems 1 and 2 is the following.

Corollary 3. If \( n \) is either prime or product of two distinct primes, then the smallest and largest distance Laplacian eigenvalue of \( \Gamma(Z_n) \) is the eigenvalue of quotient matrix.

Для скiнченного комутативного кiльця Z_n з одиничним елементом 1 ≠ 0 граф дiльникiв нуля Γ(Z_n) є простим зв’язним графом, множина вершин якого є множиною ненульових дiльникiв нуля, причому двi вершини x та y є сусiднiми тодi i тiльки тодi, коли xy = 0. Ми знаходимо дистанцiйний лапласiановий спектр графiв дiльникiв нуля Γ(Z_n) для рiзних значень n. Також ми отримуємо дистанцiйний лапласiановий спектр графа Γ(Z_n) для n = p^z, z ≥ 2, у термiнах лапласiанового спектра. Як наслiдок ми визначаємо тi значення n, для яких граф дiльникiв нуля Γ(Z_n) є дистанцiйним лапласiановим iнтегралом.

Ключовi слова i фрази: матриця Кiрхгофа, матриця Кiрхгофа вiдстаней, комутативне кiльце, граф дiльникiв нуля.
