**Investigation of The Effect of Annealing on Resistivity in Aluminum-based Amorphous Alloys**

In this study, electrical properties of Al-Y-Ni alloys produced by melt-spinning method were investigated. Before annealing, XRD analyzes were performed and the samples were found to be amorphous. Exothermic peaks were observed in DSC measurements and crystallization stages of the alloys were determined. $\text{Al}_{85}\text{Y}_{11}\text{Ni}_{4}$, $\text{Al}_{85}\text{Y}_{10}\text{Ni}_{5}$ and $\text{Al}_{85}\text{Y}_{5}\text{Ni}_{10}$ samples were annealed at some temperature and their electrical resistivities were measured by four-point method. The large decrease in resistivity was observed during crystallization between 200-400 $^\circ$C. These results were consistent with XRD and DSC measurements.

**Keywords:** amorphous alloy, crystallization, electrical resistivity.

**Introduction**

The most important feature that distinguishes amorphous alloys or metallic glasses from other alloys is that they do not have the atomic order of normal crystals and consequently do not have crystal structure. This structural and chemical state is felt in all properties and behaviors of metallic glasses, especially mechanical, chemical and electrical-magnetic. Scientists' work on amorphous alloys is quite intense [1-10]. Some properties of Al-Y-Ni alloy which is one of amorphous alloys produced by melt-spinning method. They determined phase transition temperatures by DSC measurements, annealed at these temperatures and made their X-ray analysis. They also examined in detail how the effect of ratios in alloys and the speed of the disc affect the amorphous structure [11]. Freitag et al., $\text{Al}_{83}\text{Y}_{x}\text{Ni}_{15-x}$ ($x = 3 - 12$ at.%) amorphous alloys, investigated the effect of aluminum (Al) and yttrium (Y) on resistivity at room temperature [12]. Pekala, $\text{Al}_{85}\text{Y}_{10}\text{TM}$ (TM = Cu, Ni, Co, Fe) amorphous alloys produced by melt spinning method, determined the effect of metal atoms on electron-photon interaction and examined thermoelectric power at temperatures between 20 - 300 K [13]. Again, Pekala explained the thermoelectric power and electrical resistivity of $\text{Al}_{80-x}\text{Y}_{10}\text{Ni}_{x}$ ($x = 0, 2, 5, 8$) amorphous alloys by Faber-Ziman theory. He measured the resistivity of these alloys at temperatures between 300 - 800 K by four-point method. He also examined and
compared the thermoelectric strength of these alloys in their crystalline and amorphous state [14]. Gögebakan, Al_{85}Y_{11}Ni_{4}, Al_{85}Y_{10}Ni_{5}, Al_{85}Y_{8}Ni_{7}, Al_{85}Y_{5}Ni_{10} and Al_{85}Y_{2}Ni_{13} alloys produced by melt spinning method, examined the mechanical properties, tensile strength (σf), Young’s modulus (E) and Vickers hardness (Hv) measured and compared alloys [15].

Vasiliev et al., (Al–2.6Y–9.5Ni), (Al–4.5Y–10.1Ni), (Al–4.3Y–3.5Ni) and (Al–1.7Y–6.4Ni) in atomic ratios of amorphous alloys, with electron microscopy (TEM) investigated the morphology and crystal structure of each phase. In each alloy group, they have observed the formation of α-Al, Al_{3}Ni or Al_{3}Y and a triple phase [16]. Min Young Na. et al. conducted research on thermoplastic formability and electrical conductivity in Al–Ni–Y metallic glasses [17].

In this study, electrical properties of Al-Y-Ni amorphous alloys were investigated.

I. Experimental

Samples used in this study were produced by melt-spinning technique. Production parameters of the alloys used are given in Table 1 [18].

DSC (Differential scanning calorimetry) was measured by Perkin Elmer Sapphire. X-ray diffraction analysis, Rigaku D/max-IIIC diffractometer using CuKα (λ = 1,542 Å) radiation. Measurements were carried out at room temperature in the range of 20 ≤ 2θ ≤ 90 with 0.02° steps.

Electrical measurements were made by Lucas Pro 4 device using four probe method. Here, the samples were annealed at some temperatures (not in situ), measured several times and averaged.

II. Results and discussion

Differential Scanning Calorimetry (DSC) peak patterns for Al_{85}Y_{11}Ni_{4}, Al_{85}Y_{10}Ni_{5} and Al_{85}Y_{11}Ni_{4} samples are shown in Figure 1. In the DSC analysis obtained by continuous heating, three exothermic peaks were observed for the alloys used. Figure 1 shows the crystallization temperatures T_{x} and crystallization peaks T_{1}, T_{2}, T_{3} of the samples. As can be seen from the figure, the crystallization temperature T_{x} increased with increasing amount of Y in the alloy. In X-ray diffraction analysis of samples before heat treatment, as can be seen from Figure 2, it is generally of amorphous structure.

One of the amorphous alloys (Al_{85}Y_{2}Ni_{13}) was annealed at certain temperatures and detailed XRD measurements were taken. In Figure 3 shows the X-ray diffraction patterns of the Al_{85}Y_{2}Ni_{13} sample to before annealing and annealing at 250°C, 355°C and 390°C. The minimum annealing time was set 15 minutes for each temperature. As can be seen from the figure, the diffraction pattern of the alloy before heat treatment shows a extensive peak in conformity with the amorphous structure. Samples were annealed at peak temperatures of crystallization taking DSC measurements into consideration.

It is seen that the amorphous sample annealed at T_{1} = 250 °C starts to crystallize to give crystal aluminum peaks. It is observed that the alloy continues to crystallize around T_{2} = 355 °C annealing temperature and the structure generally consists of Al and Al_{1}Y phases. At an annealing temperature of T_{3} = 390 °C, the structure is completely crystallized and generally consists of phases Al_{3}Y and Al_{3}Ni.

The samples were annealed for 15 minutes at some
temperature values between 25°C and 600°C and their resistivities were measured by four-point method at room temperature. It was observed that the resistivity of the samples decreased significantly at the temperature between which the samples started to crystallize ($T_x$) and completely crystallized ($T_3$).

Figure 4 shows the temperature-dependent resistivity of the Al$_{85}$Y$_{11}$Ni$_4$ alloy between 25°C and 600°C. In the DSC analysis shown in Figure 1, it was observed that the resistivity of the sample started to decrease at the temperature at which crystallization started ($T_x \approx 245$°C). The large drop in resistivity continued until the $T_3 = 400$°C temperature, where the sample completely crystallized.

In the Al$_{85}$Y$_{10}$Ni$_{10}$ alloy, the resistivity of the sample started to decrease at the temperature ($T_x = 240$°C) at which the crystallization started in the DSC analysis shown in Figure 1. The large drop in resistivity continued until the $T_3 = 360$°C, where the sample completely crystallized. Again in the Al$_{85}$Y$_{10}$Ni$_{10}$ sample, the resistivity of the sample began to decrease at the temperature ($T_x = 190$°C) at which the crystallization started in the DSC analysis shown in Figure 1. The large drop in resistivity continued until the $T_3 = 350$°C, where the sample completely crystallized. The reason why the resistivity drops in this way can be explained by the
transition of the semi-stable amorphous alloys to the stable (crystal) structure. In addition, it is observed that the resistivity continues to decrease at a little with the increasing of annealing temperature of the crystallized samples. This is thought to be related to the reduction of grain boundaries as a result of the growth of the particles in the alloy at high annealing temperatures. There are similar studies aluminum-based amorphous alloys and our results are compatible with them [14, 19-24]. In all alloys, a great decrease in resistivity is observed when it changes from amorphous structure to crystal structure.

**Conclusion**

In this study, electrical properties of Al-Y-Ni alloys previously obtained by melt-spinning method were investigated. The resistivity of the samples were measured by using four point technique at room temperature and annealing at some temperatures between 25°C and 600°C. X-ray analysis showed that the samples were amorphous before annealing. At the peaks obtained by DSC analysis, the crystallization temperatures of the samples were determined to be approximately 200-400°C. A significant decrease in the resistivity of the samples was observed in this temperature range. The reason for the decrease in resistivity in this way can be explained by the transition of the semi-stable amorphous alloys to stable (crystal) structure. It was observed that resistivity increased as Y ratio increased in samples. Similarly, as Ni content decreased, resistance decreased.

Investigation of The Effect of Annealing on Resistivity in Aluminum-based Amorphous Alloys

У статті досліджено електричні властивості сплавів Al-Y-Ni, отриманих методом з розплаву. Перед відпалюванням проведено XRD-аналіз та виявлено аморфність зразків. При DSC-вимірюваннях спостерігалися екзотермічні піки та визначено стадії кристалізації сплавів. Зразки Al₈₅Y₁₁Ni₄, Al₈₅Y₁₀Ni₅ та Al₈₅Y₁₀Ni₁₀ при певній відпалювали температурі, а їх електричний опір вимірювали чотиризондовим методом. Під час кристалізації в інтервалі (200 - 400) °C спостерігається суттєве пониження питомого опору. Ці результати відповідали даним, отриманим із вимірювань XRD та DSC.

Ключові слова: аморфний сплав, кристалізація, електричний опір.
