This paper aims to investigate the structural, optical and electrical properties of PEO doped with NiO. The DFT calculations have been performed using Gaussian 09 package of programs. The calculated electronic properties included the total energy, HOMO and LUMO energies, energy gap, ionization energy, electron affinity, electronegativity, electrochemical hardness, electronic softness and electrophilic index. The obtained results showed that the doping PEO with NiO improved the structural, optical, electronic and electrical characteristics where the energy band gap decreases about 67.4 % with addition of NiO which make the (PEO-NiO) composites are promising materials for flexible optoelectronics fields in the development of electronics applications.

Keywords: PEO, NiO, DFT, optical properties, electronics devices, Gaussian 09.

Introduction

Nanocomposites of organic and inorganic semiconductors dispersed in polymer matrices are multifunctional materials often suggested as elements of nonlinear optical devices and for development of plastic solar cells. The increasing interest in their possible use is caused by their plasticity, simple preparation techniques, and an opportunity to tune their properties by changing the concentration and the nanoparticle size in the matrix. A polymeric nanocomposite should possess high optical and photochemical stability [1]. Ceramic materials are typically brittle, possess low dielectric strength and in many cases are difficult to be processed requiring high temperature. On the other hand, polymers are flexible, can be easily processed at low temperatures and exhibit high dielectric breakdown fields [2]. Polymers are considered a good choice as host materials, because they normally exhibit long-term stability and possess flexible reprocessability and they can be designed to yield a variety of bulk physical properties. This new class of organic inorganic composites or hybrid materials may afford potential applications in molecular electronics, photoelectrochemical cells, optics, solvent-free coatings, etc [3]. Organic polymers show ample evidence of optical, electronic and optoelectronic properties and are at length used in optical devices like lenses, optical waveguides, optical switches, light emitting diodes and nonlinear optical applications extended use of optical polymers, it is therefore advantageous to have polymers with a property, like refractive index, within a certain range [4]. Polyethylene oxide (PEO) is a linear and semi-crystalline polymer. Because PEO is a linear polymer, the regularity of structure unit permits a high crystallinity degree. The chemical structure of PEO contains polar group –O– that can interact/associate with the cations of metal salt. Thus, PEO can solvate different types of salts. However, the reactivity is very low because of its structural unit has C–H, C–C, C–O bonds. Due to this, it is stabilized chemically and electrochemically. But a high concentration of crystalline phase within PEO polymer confines the conductivity [5]. This work aims to design of PEO/NiO structures and investigating the structural, optical and electronics properties to use in different optoelectronics and electronics devices.
I. Theoretical Part

The energy gap is calculated by the following formula[6-9]:

\[ E_{\text{gap}} = E_{\text{LUMO}} - E_{\text{HOMO}} \]  \hspace{1cm} (1)

where \( E_g \) is the energy gap, \( E_{\text{LUMO}} \) is the energy of the low unoccupied molecular orbital, \( E_{\text{HOMO}} \) is the energy of the highest occupied molecular orbital.

The total energy is the summation of total kinetic and potential energy, at the optimized structure where the total energy of the molecule must be at the lowest value due to the molecule is at the equilibrium position, which means, the of the effective forces is zero [10]. The ionization energy is expressed by the equation[11]:

\[ I_E = -E_{\text{HOMO}} \]  \hspace{1cm} (2)

Electron affinity can be given as the energy released when an electron bonds to an atom or molecule resulting in the formation of a negative ion [12].

\[ E_A = -E_{\text{LUMO}} \]  \hspace{1cm} (3)

The chemical potential (\( \mu \)) is measured the escaping tendency of electronic cloud which is given by[13]:

\[ \mu = \frac{1}{2}(E_{\text{HOMO}} + E_{\text{LUMO}}) \approx -\frac{1}{2}(I_E + E_A) \]  \hspace{1cm} (4)

Chemical hardness is calculated by [14]:

\[ H = \frac{I_E - E_A}{2} \]  \hspace{1cm} (5)

Chemical softness \( S \) is the inverse with hardness as the following equation[15]:

\[ S = \frac{1}{2H} \]  \hspace{1cm} (6)

Electrophilicity is defined by the equation [16]:

\[ \omega = \frac{\mu^2}{2H} \]  \hspace{1cm} (7)

R. Mulliken defined electronegativity as the following[17]:

\[ E_N = \frac{1}{2}(I_E + E_A) \]  \hspace{1cm} (8)

The electric dipole polarizability is the measure of the linear response of the electron density in the presence of an infinitesimal electric field \( F \) and it represents a second order variation in energy [18]. The polarizability is calculated by the following equation [19].

\[ \langle \alpha \rangle = \frac{1}{3}(\alpha_x + \alpha_y + \alpha_z) \]  \hspace{1cm} (9)

II. Results and Discussion

Geometry optimization is a standard chemistry-physical calculation to find the lowest energy or largest relaxed conformation for a molecule, it is performed by find the first derivative of the energy with respect to distance between different atoms, known as the gradient, at the stationary point this gradient is zero, since the gradient is the negative of the force, the forces are also zero at such point. The optimization structures of the pure (PEO), (PEO–NiO) nanocomposites, are seen in Figs. 1, 2. The optimized parameters of these molecules encompassed bonds in (Å) and angles in (°) calculated from DFT-B3LYP/6-31G are shown in Table 1.

Fig. 9. The distribution of HOMO(up) and LUMO(down) (PEO-NiO) structures.

Fig. 10. Electrostatic potential distribution surface for (PEO-NiO) structures.

The band gap of PEO decreases with adding of NiO, this behavior due to increase of the localized level in energy gap [22-30], which make it suitable in many optoelectronics applications.

Figure 10 illustrates the electrostatic surfaces potential distribution of structures calculated from the total self-consistent field (SCF). ESP distributions of structure are created by repulsive forces or by attracting...
regions around each structure.

Table 3 shows the results of the $E_T$ in a.u and some electronic characteristics of (PEO)\_x(NiO) and (PEO-NiO) structures calculated at the same level of theory. These properties are included $\text{IE}$, $\text{EA}$, $\text{E}_N$, $\text{H}$ and $\omega$.

Table 4 shows the polarizability average $\alpha_{\text{ave}}$ and its components in a.u of (PEO-NiO) structures.

The strength of interactions can be further studied by analyzing orbital interactions between the atoms of nanocomposite, in terms of density of states (DOS). The DOS governs many physical properties and consequently plays an important role in solid state physics, it is important to be able to predict how the DOS will behave for different molecular structures geometries.

Conclusions

This work includes the investigating the structural, optical and electrical properties of PEO doped with NiO. The DFT calculations have been performed using Gaussian 09 package of programs. Density functional theory calculations are used to study the optimized and simulated of (PEO-NiO) structures by using B3LYP/SDD basis set. The structural, optical, electronic and electrical characteristics of PEO were enhanced with adding of NiO. The energy band gap decreases about 67.4 % with addition of NiO which make the (PEO-NiO) composites are promising materials for flexible optoelectronics fields in the development of electronics applications. The final results showed the PEO/NiO structures can be used in different renewable and electronics applications.

Ключові слова: PEO, NiO, DFT, оптичні властивості, електронні пристрої, Gaussian 09.

Стаття спрямована на дослідження структурних, оптичних та електричних властивостей PEO, легованих NiO. DFT розрахунки виконано за допомогою програмного пакету Gaussian 09. Обчислени електронні властивості включали повну енергію, енергії HOMO та LUMO, ширину забороненої зони, енергію іонізації, спорідненість електронів, електронегативність, електрохімічну твердість, електронну м’якість та електрофільний індекс. Отримані результати показали, що легування PEO з NiO покращило структурні, оптичні, електронні та електричні характеристики, де ширина забороненої зони зменшується приблизно на 67,4 % із додаванням NiO, що робить композити (PEO-NiO) перспективними матеріалами для наноелектронних пристроїв.
